Course: ICT-C103

ASSIGNMENT #5

1. It is called a flow chart. It is a diagram that shows the different steps and decisions in a program. It helps developers understand and plan the program's logic before they start writing the actual code.
2. I would use a compiled language for a complex backend system because it provides faster and more efficient execution. For a simple web page, I would choose a scripting language because it is easier and quicker to develop. A compiled language is translated into machine code before the program runs, while a scripting language is usually executed line by line by an interpreter.
3. The two fundamental concepts are variables and constants. A variable is used to store a value that can change while the program is running, such as a user's information. A constant stores a value that does not change during the program's execution.
4. I would use a branch or selection structure, such as an if-else statement. It can check the current time and decide which message to display. For example, it can show a morning greeting in the morning, an afternoon greeting in the afternoon, and an evening greeting at night.
5. I would use a loop, such as a for loop. A loop allows the program to repeat the same calculation for each customer record. This saves time because I don't have to write the same calculation 100 times.
6. A procedure is used to perform a specific task, while a function performs a task and can return a value. For example, a procedure can be used to display information or update a record, while a function can calculate and return a customer's total order value. Both can make the program more organized and allow code to be reused.
7. For a Car object, its properties could include its color, brand, and speed. Its methods could include start(), stop(), and accelerate(). The class would be called Car, and it would act as a blueprint for creating different car objects. This follows the idea of OOP, where objects contain data and behaviors.
8. Two common scripting tools I could use are Windows Batch Files and Windows PowerShell. Batch files can be used for simple tasks through the Command Prompt, while PowerShell is more advanced and can be used for system administration and automation, such as managing user accounts or installing software.
9. A web application is convenient because users can access it through a web browser without having to install it on their computer. It can also be easier to update because the application is managed from the web. However, it usually depends on a network or internet connection. A locally installed application runs directly on the user's computer and can work without the internet, but it needs to be installed and maintained on each computer.
