

Name: Garcia, Marina Ellise V.

Date: July 30, 2026

Section: BSIT-102I

Course: ITC C105

1. The operating system that a person chooses affects the way they use their device every day. Windows is good for school, work, and gaming because it supports many applications. macOS works best with Apple devices and is popular for creative work. Linux is open-source and is often used by programmers. Android and iOS are designed for mobile devices and have different apps and features. I think choosing the right OS depends on what a person needs and the apps they use the most.
2. A **GUI** lets users interact with the computer using windows, icons, menus, and buttons. A **CLI** lets users type commands instead of clicking on icons. Most people use a GUI because it is easier to learn. However, some users prefer a CLI when they need to do advanced tasks, troubleshoot problems, or run commands more quickly.
3. When a computer is turned on, it first checks if the important hardware is working correctly through the Power-On Self-Test (POST). If everything is okay, the operating system loads and the computer become ready to use. If an important part of the POST fails, the computer may not continue booting. It could show an error message, make beep sounds, or stay on a black screen because it cannot start the operating system properly.
4. Multitasking means running more than one application at the same time. Operating systems like Windows and macOS manage the computer's resources so different programs can work together smoothly. For example, I can attend an online class while taking notes in Microsoft Word and listening to music. The taskbar and switching between windows help me move from one app to another easily.
5. A device driver is software that allows the operating system to communicate with hardware like printers, keyboards, or graphics cards. They are important because without the correct driver, the operating system may not recognize or use the device properly. If a driver is missing or outdated, the hardware might not work or could have limited features.
6. A file system organizes files into folders and subfolders. This creates a hierarchy that makes it easier to store and find files. For example, I can create a folder called **School**, then make separate folders for each subject like **Math** and **English**. This helps keep my files organized and prevents them from getting mixed up.
7. A user account lets each person have their own files, settings, and preferences on a computer. A **standard user account** can use programs but cannot make major system changes. An **administrator account** has permission to install software, change settings, and manage other users. It is safer to use a standard account for daily tasks because it helps prevent accidental changes and protects the computer from harmful software.

8. File and folder permissions control who can view, edit, or delete files. For example, if I finish a school project, I can set it to **read-only** before sharing it with classmates. This allows them to read the file but prevents them from accidentally changing or deleting my work.
9. The operating system manages important resources like the CPU, RAM, and storage so different applications can run properly. It decides how much memory and processing power each program can use. This prevents one application from using all the computer's resources, helping the system stay stable and responsive.
10. I would use **Disk Cleanup** when my computer is running out of storage because it removes temporary files and other unnecessary data. This frees up space and can help the computer run more smoothly. Another useful utility is **Task Manager**, which lets me see which programs are using the most resources so I can close apps that are slowing down my computer.
