Midterms Assignment 7

1. A database table has columns (fields) and rows (records). Columns can store Name, Phone Number, and Email, while each row represents one contact. A primary key can uniquely identify each contact.
2. The process is called a query. The common language used to retrieve information from a database is SQL (Structured Query Language).
3. An RDBMS is better because it can:
 - Handle large amounts of data more efficiently.
 - Link multiple tables and help keep data accurate and secure.
4. A foreign key in the Orders table connects to the primary key in the Customers table. This keeps the customer and order information properly connected and maintains data integrity.
5. Customer reviews are unstructured data because they are free-form text. Customer profiles are structured data because they are organized in rows and columns. Structured data is easier to store and analyze using relational databases.
6. I would use DML, specifically the UPDATE command. DDL changes the database structure, while DML changes or retrieves the records stored in the database.
7. In a client-server architecture, the client runs the application while the server stores and manages the database. Using a three-tier design can make the application easier to update and expand because the presentation, business logic, and data are separated.
